Both peroxisome proliferator-activated receptor (PPAR)-gamma and Both peroxisome proliferator-activated receptor (Fran)-gamma and hormone-sensitive lipase (HSL) play important roles in lipid metabolism and insulin sensitivity. We demonstrate that expression of the HSL gene is up-regulated by PPAR gamma and PPAR gamma agonists (rosiglitazone and pigglitazone) in the cultured hepatic cells and rosiglitazone and pioglitazone) in the cultured hepatic cells and differentiating preadipocytes. Rosiglitazone treatment also results in up-regulation of the HSL gene in liver and skeleton muscle from an experimental obese rat model, accompanied by the decreased triglyceride content in these tissues. The proximal promoter (-87 bp of the human HSL gene) was found to be essential for PPAR gamma-mediated transactivating activity. This important promoter region contains two GC-boxes and binds the transcription factor specificity protein-1 (Sp1) but not PPAR gamma and rosiglitazone, as demonstrated by analysis of EMSA and chromatin immunoprecipitation assay. Mutations in the GC-box sequences reduce the promoter binding activity of Sp1 and the transactivating activity of PPAR gamma. In addition, mithramycin A, the specific inhibitor for Sp1-DNA binding activity, abolishes the PPAR gamma-mediated up-regulation of HSL. These results indicate that PPAR gamma positively regulates the HSL gene expression, and up-regulation of HSL by PPAR gamma requires the involvement of Sp1. Taken together, this study suggests that HSL may be a newly identified PPAR gamma target gene, and up-regulation of HSL may be an important mechanism involved in action of PPAR gamma agonists in type 2 diabetes.
